HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers. L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
PD+ Attitude Control of Rigid Bodies with Improved Performance

Rune Schlanbusch, Antonio Loría, Raymond Kristiansen and Per Johan Nicklasson

Abstract—We address the problem of state feedback attitude control of a rigid body in quaternion coordinate space through a modified PD+ tracking controller. The control law ensures faster convergence to the desired operating point during attitude maneuver, while keeping the gains small for station keeping. A direct consequence is a drop in energy consumption when affected by sensor noise. More precisely, we show uniform asymptotic stability for the system without perturbations and uniform practical asymptotic stability in the presence of unknown, bounded input disturbances. Simulation results illustrate the performance improvement with respect to classic PD+ control, especially in the presence of input perturbations.

I. INTRODUCTION

Attitude control on the rotational sphere is an interesting theoretical problem since, due to the parametrization of the attitude for the unit quaternion, the model has multiple equilibrium points. From a more practical viewpoint, besides achieving stability in some sense, control of a rigid body demands fast and accurate settling using minimal effort. Thus, a wide number of controllers have been developed during the past years, by focusing on the enhancement of performance while guaranteeing robust stability and minimizing the control effort.

Attitude tracking control naturally lies on a bulk of literature on tracking control of robot manipulators and, more generally Euler-Lagrange systems cf. [1]. A classic in robot control literature is the PD+ controller of Paden and Panja cf. [2] which, together with the Slotine and Li controller [3], was the first algorithm for which global asymptotic stability was demonstrated. A PD+ based controller for spacecraft was presented in [4], called model-dependent control, and more recently for leader-follower spacecraft formation in [5].

In this paper we use a modified PD+ controller which, roughly speaking, includes nonlinear gains of exponential growth. That is, for large errors the controller ensures fast convergence; on the other hand, the control effort is reduced exponentially in a neighborhood of the reference operating point. Consequently, very little control effort is used in station-keeping tasks, especially in the presence of sensor noise. Strictly speaking, we show that the origin of the closed-loop system is uniformly practically asymptotically stable with respect to perturbations. Our theoretical findings are validated in simulation for an Earth orbiting spacecraft.

A range of results are presented to compare performance of the modified PD+ controller relative to the classical one.

II. PRELIMINARIES

The cross product operator \( \times \) between two vectors \( \mathbf{a} \) and \( \mathbf{b} \) is written as \( \mathbf{S}(\mathbf{a})\mathbf{b} \) where \( \mathbf{S} \) is skew-symmetric. The symbol \( \omega_{b:a} \) denotes angular velocity of frame \( a \) relative to frame \( b \), expressed in the frame \( c \); \( R_{b}^{a} \) is the rotation matrix from frame \( a \) to frame \( b \); \( \| \cdot \| \) denotes the Euclidean norm. Coordinate reference frames are denoted by \( \mathcal{F}^{(i)} \), where the superscript denotes the frame in question. When the context is sufficiently explicit, we omit the arguments of functions.

A. Cartesian Coordinate Frames

The coordinate reference frames used throughout the paper are defined as follows:

**Earth-centered inertial frame:** The Earth-centered inertial (ECI) frame is denoted \( \mathcal{F}^{0} \), and has its origin in the center of the Earth. The axes are denoted \( x^{i}, y^{i}, z^{i} \), where the \( z^{i} \) axis is directed along the axis of rotation of the Earth toward the celestial North Pole, the \( x^{i} \) axis is pointing in the direction of \( \Upsilon \), which is the vector pointing from the center of the Sun toward the center of the Earth during the vernal equinox, and finally the \( y^{i} \) axis completes the right handed orthonormal frame.

**Spacecraft orbit reference frame:** The orbit frame, denoted \( \mathcal{F}^{o} \), has its origin located in the center of mass of the spacecraft. The \( x^{o} \) axis in the frame coincides with the vector \( r^{i} = [r_{x}, r_{y}, r_{z}]^{T} \in \mathbb{R}^{3} \) from the center of the Earth to the spacecraft, and the \( z^{o} \) axis is parallel to the orbital angular momentum vector, pointing in the orbit normal direction. The \( y^{o} \) axis completes the right-handed orthonormal frame. The basis vectors of the frame can be defined as

\[
x^{o} := \frac{r^{i}}{r}, \quad y^{o} := \mathbf{S}(x^{o})x^{o} \quad \text{and} \quad z^{o} := \frac{h^{i}}{h},
\]

where \( h^{i} = \mathbf{S}(r^{i})r^{i} \in \mathbb{R}^{3} \) is the angular momentum vector of the orbit, \( h = \|h^{i}\| \) and \( r = \|r^{i}\| \). This frame is also known as the Local Vertical/Local Horizontal (LVLH) frame.

**Body reference frame:** The body frame is denoted \( \mathcal{F}^{b} \), and is located at the center of mass of the rigid body, and its basis vectors are aligned with the principle axis of inertia.

**Auxiliary orbit frame:** Because of the nature of the aerodynamic drag and the fact that it always acts along the velocity vector of the spacecraft we need an auxiliary orbit frame, denoted \( \mathcal{F}^{a} \), when elliptic orbits are considered. The first basis vector is parallel with the orbit frame such that \( x^{a} \parallel x^{o} \),
\[ y^a \] is pointing in the direction of the spacecraft velocity vector, and \( z^a \) is completing the right-handed orthonormal frame. A rotation between the auxiliary frame and the LVLH frame is expressed as \[ C^a_o = \frac{h}{\mu} \begin{bmatrix} \frac{h}{\mu} & e \sin \nu & 0 \\ -e \sin \nu & \frac{h}{\mu} & 0 \\ 0 & 0 & \mu \end{bmatrix}, \] (2)

where \( p = h^2/\mu \) is the semi-latus rectum of the spacecraft orbit, \( \mu \) is the geocentric gravitational constant of the Earth, \( v \) is the magnitude of the velocity vector, \( e \) is the orbit eccentricity, and \( \nu \) is the true anomaly. Note that \( C^a_o \) is not in general a proper rotation matrix since

\[ \det C^a_o = 1 + e^2 + 2e \cos \nu. \]

B. Quaternions

The attitude of a rigid body is often represented by a rotation matrix \( R \in SO(3) \) fulfilling

\[ SO(3) = \{ R \in \mathbb{R}^{3 \times 3} : R^T R = I, \det R = 1 \}, \]

which is the special orthogonal group of order three. Quaternions are often used to parameterize members of \( SO(3) \) where the unit quaternion is defined as \( \mathbf{q} = [\eta, \mathbf{e}]^T \in S^3 = \{ \mathbf{x} \in \mathbb{R}^4 : \mathbf{x}^T \mathbf{x} = 1 \} \), where \( \eta \in \mathbb{R} \) is the scalar part and \( \mathbf{e} \in \mathbb{R}^3 \) is the vector part. The rotation matrix may be described by \[ R = I + 2\eta S(\mathbf{e}) + 2S^2(\mathbf{e}) \] (3)

with \( \mathbf{e} = [e_x, e_y, e_z]^T \), where the matrix \( S(\cdot) \) is the cross product operator

\[ S(\mathbf{e}) = \mathbf{e} \times = \begin{bmatrix} 0 & -e_z & e_y \\ e_z & 0 & -e_x \\ -e_y & e_x & 0 \end{bmatrix}. \]

The inverse rotation can be performed by using the inverse conjugated of \( \mathbf{q} \) as \( \bar{q} = [\eta, -\mathbf{e}]^T \). The set \( S^3 \) forms a group with quaternion multiplication, which is distributive and associative, but not commutative, and the quaternion product of two arbitrary quaternions \( \mathbf{q}_1 \) and \( \mathbf{q}_2 \) is defined as \[ \mathbf{q}_1 \otimes \mathbf{q}_2 = \begin{bmatrix} \eta_1\eta_2 - \mathbf{e}_1 \mathbf{e}_2 \\ \eta_1\mathbf{e}_2 + \eta_2\mathbf{e}_1 + S(\mathbf{e}_1)\mathbf{e}_2 \end{bmatrix}. \]

It must be noted that the quaternion representation is inherently redundant therefore, it admits two mathematically different equilibria \( \mathbf{q}_1 \otimes \mathbf{q}_2 = [\pm 1, 0]^T \) which in fact represent the exact same physical orientation \( i.e., \) one is rotated by \( 2\pi \) rad relative to the other about an arbitrary axis.

C. Kinematics and Dynamics

The time derivative of (3) can be written as [7]

\[ \dot{R}^a_b = S(\omega^a_{a,b})R^a_b = R^a_b S(\omega^b_{a,b}), \]

and the kinematic differential equations can be expressed as [7]

\[ \dot{q} = T(q)\omega^b_{i,b}, \] (4)

where

\[ T(q) = \frac{1}{2} \begin{bmatrix} -\mathbf{e}^T \\ \eta + S(\mathbf{e}) \end{bmatrix} \in \mathbb{R}^{4 \times 3}. \]

The dynamical model of a rigid body can be described by a differential equation for angular velocity, and is deduced from Euler’s moment equation. This equation describes the relationship between applied torque and angular momentum on a rigid body as [8]

\[ J \dot{\omega}_{i,b} = -S(\omega^b_{i,b})J \omega^b_{i,b} + \tau^b \] (5)

\[ \omega^b_{i,b} = \omega^b_{i,b} - R^b_i \omega^i_{o,\nu}, \] (6)

\[ \omega^i_{i,o} = S(r^i)v^i \] (7)

where \( v^i \in \mathbb{R}^3 \) is the spacecraft velocity vector in inertial frame, \( \tau^b \in \mathbb{R}^3 \) is the total torque working on the body frame, and \( J = \text{diag}(J_x, J_y, J_z) \in \mathbb{R}^{3 \times 3} \) is the inertia matrix where \( J_x, J_y \), and \( J_z \) are the moments of inertia of the body about its three orthonormal axes. The torque working on the body is expressed as \( \tau^b = \tau^a + \tau^d \), where \( \tau^d \) is the disturbance torque, and \( \tau^a \) is the actuator (control) torque. Usually the desired trajectory is given in the orbit frame such as \( \omega^o_{o,d} \), which means that (6) has to be used as state, which leads to an increased complexity of the control structure as in [9]. Instead we add (6) and its derivative to the generated reference such that \( \omega^o_{i,d} = \dot{R}^o_i \omega^i_{o,\nu} + R^o_i \omega^o_{o,d} \). Throughout the paper we will denote \( \omega = \omega^o_{i,b} \).

D. Disturbances

Since a spacecraft in an elliptic Low Earth Orbit (LEO) is considered for our simulations, we only consider the disturbance torques which are the major contributors to these kind of orbits, namely: gravity gradient, and torques caused by atmospheric drag and \( J_2 \) effect. Gravity gradient torque is forcing the spacecraft to align its axis of minimum moment of inertia vertically and can be expressed as [8]

\[ \tau^b_{gg} = R^b_s S(r^i)Jr^i. \]

The atmospheric drag can be expressed as [10]

\[ f^b_{atm} = R^b_s C^a \begin{bmatrix} -\frac{1}{2} \rho v^2 C_d A \\ 0 \end{bmatrix}, \]

where \( \rho \) is the atmospheric density, \( v \) is the spacecraft velocity, \( C_d \) is the drag coefficient and \( C^a \) as in (2), and \( f \in \mathbb{R}^3 \) denotes an translational acceleration vector working on the spacecraft. The \( J_2 \) effect is caused by non-homogeneous mass distribution of a planet, and for Earth a simplified model can according to [11] be expressed as

\[ f^b_{grav} = \frac{3}{2} \mu J_2 R^b_s R^b_s \begin{bmatrix} 5\frac{v^2}{r^2} - 3\frac{v^2}{r^2} \\ 5\frac{v^2}{r^2} - 3\frac{v^2}{r^2} \\ 5\frac{v^2}{r^2} - 3\frac{v^2}{r^2} \end{bmatrix}. \]
where $J_2 = 1082.6 \cdot 10^{-6}$ and $R_e$ is the mean equatorial radius of the Earth. The rotational torque caused by perturbing forces can be found from the relation [7]

$$\tau^b_j = S(r^b_j)^T \tau^b,$$

where $r^b_j$ is the vector from the spacecraft center of mass to the line of action of the force. Hence the total disturbance torque may be written as

$$\tau^b_d = \tau^b_{gg} + S(r^b_j)(F^b_{num} + F^b_{grav}).$$

### III. CONTROL OF RIGID BODY

#### A. Problem Formulation

The control problem is to steer the state $q(t)$ towards a given reference trajectory $q_d(t)$ satisfying the kinematic equation

$$\dot{q}_d = T(q_d)\omega_d.$$

The tracking error in quaternion coordinates, $\tilde{q} = [\tilde{\eta}, \tilde{\epsilon}^\top]^\top$, is given by

$$\dot{\tilde{q}} := \tilde{q} \otimes \tilde{q}_d = \begin{bmatrix} \eta \eta_d + \epsilon^\top \epsilon_d \\ \eta \epsilon_d - \eta \epsilon_d - S(\epsilon) \epsilon_d \end{bmatrix},$$

and the quaternion velocities may be expressed as (cf. [12])

$$\dot{\tilde{q}} = T(\tilde{q}) (\omega - \omega_d).$$

For the purpose of establishing meaningful stability properties we define the error functions

$$e_{q \pm} = [1 \mp \tilde{\eta}, \tilde{\epsilon}^\top]^\top, \quad e_\omega = \omega - \omega_d.$$

Moreover, we have

$$\dot{e}_{q \pm} = T_c(e_{q \pm}) e_\omega,$$

where

$$T_c(e_{q \pm}) = \frac{1}{2} \begin{bmatrix} \mp \tilde{\epsilon}^\top \\ \tilde{\eta} I + S(\epsilon) \end{bmatrix}.$$

**Remark 3.1:** Due to the redundancy implicit to the quaternion representation, $\tilde{q}$ and $-\tilde{q}$ represent the same physical attitude but correspond to different equilibria. That is, the two attitude positions differ by a rotation of $2\pi$ rad about an arbitrary axis. Consequently, in quaternion coordinates it is not appropriate to speak of global stability properties. This has often been overlooked in the literature.

#### B. Uniform Asymptotic Stabilization

Assume, for the time-being that the disturbances $\tau^b_d$ are known. Consider the PD+ control law

$$\tau^b_a = J\omega_d - S(J\omega_d)\omega_d - \tau^b_d - k_p T_c^\top e_q - k_d e_\omega.$$  \hspace{1cm} (8)

The following proposition establishes uniform asymptotic stability of the closed-loop system under a modified PD+ controller.

**Proposition 3.1:** Let $e_q$ be defined either by $e_q = e_{q+}$ or $e_q = e_{q-}$ and respectively, let $\tilde{\eta}(t_0) \geq 0$ or $\tilde{\eta}(t_0) < 0$, and assume that $\text{sgn}(\tilde{\eta}(t_0)) = \text{sgn}(\tilde{\eta}(t))$ for all $t > t_0$, and assume that the desired attitude $q_d(t)$, desired angular velocity $\omega_d(t)$ and the desired angular acceleration $\dot{\omega}_d(t)$ are all bounded functions. The dual equilibrium points $(e_{q+}, e_{\omega}) = (0, 0)$ of the system (4) and (5), in closed-loop with the control law

$$\tau^b_a = J\omega_d - S(J(\omega_d)\omega_d - \tau^b_d - k_p e^{k_1 e_q} T_c^\top e_q - k_d e^{k_2 e_\omega} e_\omega,$$

where $k_p > 0, k_d > 0, k_1 > 0$ and $k_2 > 0$ are feedback gains, are uniformly asymptotically stable (UAS).

**Proof:** Without loss of generality, we show stability of the positive equilibrium point i.e., let $e_q = e_{q+}$ and $T_c = T_c(e_{q+})$.

The closed-loop dynamics that results from substituting (9) in (5) is

$$\dot{e}_\omega = J^{-1} (S(J(\omega_d)e_\omega - k_p e^{k_1 e_q} T_c^\top e_q - k_d e^{k_2 e_\omega} e_\omega).$$

Consider the radially unbounded and positive definite Lyapunov function candidate

$$V(x) = \frac{1}{2} \left( k_p \left( e^{k_1 e_q} e_q - 1 \right) + e_\omega^\top J e_\omega \right),$$

with lower and upper bounds

$$\kappa(\|x\|) = \frac{1}{2} \min \left\{ \frac{k_p}{k_1}, j_M \right\} \|x\|^2$$

$$\pi(\|x\|) = \frac{1}{2} \max \left\{ \frac{k_p}{k_1}, j_M \right\} \left( e^{k_1 \|x\|^2} - 1 \right)$$

where $x = [e_q^\top, e_\omega^\top]^\top$, $j_M \leq \|x\| \leq J_M$. The total time derivative of $V$ along the closed-loop trajectories generated by (7) and (10) yields

$$\dot{V}(x) = k_p e^{k_1 e_q} e_q T_c^\top e_\omega + e_\omega^\top S(J(\omega_d)e_\omega - e_\omega^\top J e_\omega - e_\omega^\top k_p e^{k_1 e_q} e_q T_c^\top e_q - e_\omega^\top k_d e^{k_2 e_\omega} e_\omega$$

$$\leq -e_\omega^\top k_2 e_\omega \leq 0,$$

where we have used that $k_2 > 0$ and $S(J(\omega_d)$ is skew-symmetric. We conclude that the equilibrium point $(e_{q+}, e_{\omega}) = (0, 0)$ is uniformly stable and the solutions are uniformly bounded.

For uniform asymptotic stability we invoke Matrosov’s theorem as stated in [2]. To that end, we introduce the auxiliary function

$$W(x) = e_q^\top T_c J e_\omega$$

which is continuous and uniformly bounded on compacts of the state. The total time derivative of $W$ along closed-loop
trajectories yields
\[
\dot{W}(x) = e_q^T \dot{T}_e \dot{e}_\omega + e_q^T T_e \dot{e}_\omega + e_q^T T_e \dot{e}_\omega \\
- e_q^T T_e \left( - S(J\omega) + k_d e_k e_\omega - \dot{e}_\omega \right) e_\omega \\
+ k_p e_k e_\omega e_q^T T_e e_\omega.
\]  
(12)

We now verify that $\dot{W}$ is non-zero definite on the set $E = \{ \dot{V} = 0 \} = \{ e_\omega = 0 \}$. To that end observe that
\[
e_\omega = 0 \Rightarrow \dot{W}(x) = - e_q^T T_e k_p e_k e_\omega e_q T_e e_\omega.
\]  
(14)

We claim that
\[
\dot{W}(x) \leq -e_q^T T_e k_p e_k e_\omega e_q T_e e_\omega.
\]  
(15)

To see this we first notice that
\[
e_q^T T_e T_e^T e_q = \frac{1}{4} e^T \dot{e}.
\]  
(16)

Also, in view of (7) we have
\[
\frac{1}{8} \left( (1 - \dot{\eta})^2 + \dot{e}^T \dot{e} \right) = \frac{1}{8} e_q^T e_q.
\]  
(17)

Now, assume that
\[
\frac{1}{4} e^T \dot{e} < \frac{1}{8} \left( (1 - \dot{\eta})^2 + \dot{e}^T \dot{e} \right)
\]  
which is equivalent to
\[
(1 - \dot{\eta})^2 > \dot{e}^T \dot{e}.
\]  
(18)

In view of the quaternion constraint $\dot{e}^T \dot{e} = 1 - \dot{\eta}^2$ inequality (18) holds if and only if $2\dot{\eta}(1 - \dot{\eta}) > 0$. In its turn, the latter holds only if $\dot{\eta} < 0$ or $\dot{\eta} > 1$. However, this does not hold by assumption i.e., $\dot{\eta} \in [0, 1]$. We conclude that (17) does not hold. Therefore, from (16)-(18) we obtain that
\[
e_q^T T_e T_e^T e_q \geq \frac{1}{8} e_q^T e_q
\]  
which together with (14) and $k_1 \geq 0$ implies (15). That is, $\dot{W}$ is non-zero definite on $E$. Uniform asymptotic stability follows invoking Matrosov’s theorem.

The proof for the negative equilibrium point $e_{q-}, T_e(e_{q-})$ follows along the same lines. We conclude that the dual equilibrium points $(e_{q+}, e_\omega) = (0, 0)$ are uniformly asymptotically stable.

\[ \square \]

C. Uniform Practical Asymptotic Stability

In the previous section, uniform asymptotic stability clearly follows under the assumption that $\tau_d^b$ is known and accounted for in the control law. In this section we relax this assumption and assume that $\tau_d^b$ is unknown, but bounded. More precisely, we assume that there exists $\beta_d > 0$ such that $\|\tau_d^b\| \leq \beta_d$.

**Proposition 3.2:** Let $e_q$ be defined either by $e_q = e_{q+}$ or $e_q = e_{q-}$ and respectively, let $\dot{\eta}(t_0) \geq 0$ or $\dot{\eta}(t_0) < 0$. Assume that $\text{sgn}(\dot{\eta}(t_0)) = \text{sgn}(\dot{\eta}(t))$ for all $t > t_0$. Assume further that the desired attitude $q_d(t)$, desired angular velocity $\omega_d(t)$ and the desired angular acceleration $\dot{\omega}_d(t)$ are all bounded functions. Then, the dual equilibrium points $(e_{q+}, e_\omega) = (0, 0)$ of the system (4) and (5), in closed loop with the control law
\[
\tau_d^b = J\omega_d - S(J\omega)\dot{\omega}_d \\
- k_p e_k e_\omega e_q T_e e_q - k_d e_k e_\omega e_\omega + \beta_d e_q T_e e_\omega,
\]  
(19)

where $k_p > 0$, $k_d > 0$, $k_1 > 0$ and $k_2 > 0$ are feedback gains, are uniformly practically asymptotically stable (UPAS).

**Proof:** We start by considering the positive equilibrium point such that $e_q = e_{q+}$ and $T_e = T_e(e_{q+})$. By inserting the control law (19) into (5) we obtain the closed-loop dynamics
\[
e_\omega = J^{-1} \left( S(J\omega) e_\omega - k_p e_k e_\omega e_q T_e e_\omega \\
- k_d e_k e_\omega e_\omega + \tau_d^b \right).
\]  
(20)

The total time derivative of $V$ defined in (11) along the closed-loop trajectories generated by (7) and (20) yields
\[
\dot{V} \leq -e_q^T T_e k_p e_k e_\omega e_q + \beta_d \|e_\omega\|.
\]  
(21)

Let $\delta := \beta_d / k_d$. From the expression above, we have $\dot{V} < 0$ if $\|e_\omega\| > \delta$. Since $V$ is positive definite and proper we obtain that $\|e_\omega(t)\|$ is bounded that is, for any $r > 0$ there exists $\Delta(r) > 0$ such that $\|e_\omega(t)\| < \Delta$ for all initial conditions $\|x(t_0)\| < r$, $t_0 \geq 0$.

For any $\Delta$, let $\lambda(\Delta) > 0$ be a constant to be determined. Consider the Lyapunov function candidate
\[
\dot{V}(x) = V(x) + \lambda W(x)
\]  
which is positive definite and proper for $\lambda \leq 1$. Its total time derivative along the closed-loop trajectories yields
\[
\dot{V}(x) = -e_q^T k_d e_k e_\omega e_\omega + \beta_d \|e_\omega\| + \lambda e_\omega^T T_e^T T_e e_\omega \\
+ \lambda e_q^T T_e T_e e_\omega + \lambda e_q^T T_e \left( S(J\omega) - k_d e_k e_\omega e_q T_e e_\omega \right) e_\omega \\
- \lambda e_q^T T_e k_p e_k e_\omega e_q T_e e_q + \lambda \beta_d \|e_q^T T_e e_\omega\|.
\]  
By inserting $T_e e_\omega = G(q)e_\omega$, where $G(q) = 1/2[e_\omega + S(e)] - 1/4$, and notice that $\|T_e T_e\| = 1/4$ and $\|e_q T_e^T\| \leq \|e_\omega\|$, we obtain
\[
\dot{V}(x) \leq -e_q^T k_d e_k e_\omega e_\omega + \frac{\lambda}{2} e_\omega^T \left( I + S(e) \right) J e_\omega \\
+ \lambda e_q^T T_e \left( S(J\omega) - k_d e_k e_\omega e_q T_e e_\omega \right) e_\omega \\
- \lambda e_q^T T_e k_p e_k e_\omega T_e e_q + 2\beta_d \|x\| \\
= -x^T P x + 2\beta_d \|x\|,
\]  
where we defined $P = [p_{ij}]$, $i, j = 1, 2$ with
\[
p_{11} = k_d e_k e_\omega e_q T_e I - \frac{\lambda}{2} e_\omega^T \left( I + S(e) \right) J \\
p_{12} = \frac{\lambda}{2} T_e \left( -S(J\omega) + k_d e_k e_\omega T_e \right) \\
p_{22} = \lambda T_e k_p e_k e_\omega T_e^T .
\]
Notice that for any \( \|e_ω\| \leq \Delta \) and \( \|ω_d\| \leq β_ω d \) which hold under the arguments made so far, the angular velocities \( ω = e_ω + ω_d \) satisfy the bound \( \|ω\| \leq ζ(Δ, β_ω d) \) for some number \( ζ > 0 \). Therefore, \( \|S(Jω)\| \leq ζ(Δ, β_ω d, J_M) \) for some number \( ζ > 0 \).

Next, we use 2(\|a\| \leq a^2 + b^2 \) for any \( a, b \in \mathbb{R} \) to obtain

\[
x^\top P x \geq (p_{11,m} - p_{12,M})\|e_q\|^2 + (p_{22,m} - p_{12,M})\|e_ω\|^2.
\]

where \( p_{ij,m} \) and \( p_{ij,M} \) denote lower and upper bounds on the induced norms of the sub-blocks \( p_{ij} \) of \( P \) respectively.

Hence,

\[
p_{11,m} \geq 2p_{12,M}, \quad p_{22,m} \geq 2p_{12,M}, \tag{22}
\]

resulting in

\[
x^\top P x \geq \frac{1}{2} (p_{11,m}\|e_q\|^2 + p_{22,m}\|e_ω\|^2).
\]

To fulfill (22) we need to choose

\[
λ \leq \frac{2k_d}{ζ(Δ, β_ω d, J_M) + k_d e^{k_d Δ^2/2} + J_M},
\]

\[
k_p \geq \left[ \frac{2}{ζ(Δ, β_ω d, J_M) + k_d e^{k_d Δ^2/2}} \right],
\]

Thus,

\[
\hat{V} \leq -p_m\|x\|^2 + 2β_d\|x\|,
\]

where \( p_m > 0 \) is a uniform lower bound on the smallest eigenvalue of \( P(\cdot) \). The derivative \( \hat{V} < 0 \) for all states such that \( \|x\| > θ' := 2β_d/p_m \). Note that \( p_m \) depends on the controller gains monotonically hence the closed-loop trajectories system converge from any ball of initial conditions in the state space to a ball in close vicinity of the origin, of radius \( θ' \). Moreover, the latter may be reduced at will by increasing the control gains. We conclude that the equilibrium point \( (e_q, e_ω) \to (0, 0) \) is uniformly practically asymptotically stable.

The proof for the negative equilibrium point \( e_{q−}, T_e(e_{q−}) \) follows along similar lines hence, the dual equilibrium points \( (e_{q±}, e_ω) = (0, 0) \) are uniformly practically asymptotically stable.

### IV. SIMULATION RESULTS

We present now some simulation results for a spacecraft on an elliptic LEO. The simulations were performed in Simulink using a variable sample-time Runge–Kutta ODE45 solver with relative and absolute tolerances of \( 10^{-9} \). The moments of inertia were chosen as \( J = \text{diag}(4.35, 4.33, 3.664) \) kgm², and the spacecraft orbit was chosen with perigee at 600 km, apogee at 750 km, inclination at 71°, and the argument of perigee and the right ascension of the ascending node at 0°.

For sake of comparison, we performed simulations using the PD+ controller

\[
\tau_a^b = Jω_d - S(Jω)ω_d - k_p T_e^\top e_q - k_d e_ω. \tag{23}
\]

as well as the modified PD+ controller. To evaluate and compare the performance of the controllers we use the functionals

\[
J_q = \int_{t_0}^{t_f} e_q^\top e_q dt, \quad J_ω = \int_{t_0}^{t_f} e_ω^\top e_ω dt, \quad J_p = \int_{t_0}^{t_f} τ_a^\top τ_a dt,
\]

where \( t_0 \) and \( t_f \) defines the start and end of the simulation window, respectively. The functional \( J_q \) and \( J_ω \) describes the integral functional error of the attitude and angular velocity error, while \( J_p \) describes the integral of the applied control torque.

We introduce measurement noise as \( σ_ω B^n = \{ x ∈ \mathbb{R}^n : \|x\| ≤ σ \} \) and add a suitable amount to the error functions according to \( \tilde{e}_q = (e_q + 0.05 B^q)/\|e_q + 0.05 B^q\| \) and \( \tilde{e}_ω = e_ω + 0.01 B^3 \) which represent a poor spacecraft navigational system. Disturbances are added according to Section II-D with \( ρ_c^b = [0.1, 0, 0]^\top \). For our simulations we have chosen the initial conditions as \( q = [-0.3772, -0.4329, 0.6645, 0.4783]^\top \) and \( ω = [0.1, -0.3, 0.2]^\top \), \( t_0 = 0 \) s, \( t_f = 30 \) s. The control laws were tuned to achieve similar performance for sake of comparison thus using parameters \( k_p = k_d = 2 \) for (23), and \( k_p = 1, k_d = 1.6 \) and \( k_l = k_q = 1 \) for (19).

The simulation results are summarized in Table I and depicted in Figure 1. The performance functionals show that both controllers have similar performance though the ordinary controller has slightly higher attitude and angular velocity error while the power consumption is slightly lower.

The simulation results for one orbital period (5896 s) is presented in Table II and as can be seen the performance functionals are less affected for (19) compared to (23). This is because as \( e_q \approx 0 \) and \( e_ω \approx 0 \), the controller gains for (19) are \( k_p e^{k_p \epsilon_1 e_q} \approx k_p \) and \( k_d e^{k_d \epsilon_1 e_ω} \approx k_d \) and since the gains \( k_p \) and \( k_d \) are smaller for (19) compared to (23) for a similar maneuver, the noise has less effect on the performance functionals.

In Table III we present simulation results from a wide number of simulations for a general rigid-body without disturbances and noise with controller gains \( k_p = 2, k_d = 1 \) for both (8) and (9), and using random initial values for the quaternion vector, while the initial angular velocity was found randomly with standard deviation in equal steps from

0.01 to 0.5 rad/s during 10,000 consecutive runs. This is done to show that the exponential gains makes the system work faster than constant gains, for the price of increased power consumption.

V. CONCLUSION

We improved the existing PD+ control law by introducing exponentially proportional and derivative gains for control of a rigid body. It was showed that the equilibria of the closed-loop system with known disturbances are uniformly asymptotically stable and uniformly practically asymptotically stable under the effect of disturbances. Simulation results show that, in terms of integrated error and power consumption the proposed controller is much less affected by sensor noise. Simulations also show that the proposed controller in general works faster than the ordinary PD+ controller with an increase in power consumption.
