Constrained control of uncertain, time-varying linear discrete-time systems subject to bounded disturbances

H.-N. Nguyen†, S. Olaru‡, P.-O. Gutman†, M. Hovd‡

Abstract—The aim of this paper is twofold. In the first part, robust invariance for ellipsoidal sets with respect to uncertain and/or time-varying linear discrete-time systems with bounded additive disturbances is revisited. We provide an extension of an existing invariance condition. In the second part a novel robust interpolation based control design involving several local unconstrained robust optimal controls is proposed. At each time instant a quadratic programming problem is solved on-line. Proofs of recursive feasibility and input-to-state stability are given.

I. INTRODUCTION

In this paper we consider robust control of uncertain and/or time-varying linear discrete-time systems affected by bounded additive disturbances. Input, state and disturbance constraints are taken into account in the control design. This control problem has been tackled with e.g. invariant set methods [1], or model predictive control (MPC) [2].

In the MPC context, one approach is to formulate a min-max optimization problem [3] which is NP-hard. In [4] tube-MPC is proposed for nominal systems with bounded disturbances. The design is complicated and it is non-trivial to extend it to uncertain and/or time-varying plants.

Here interpolating robust constrained control is considered. On-line interpolation is not a new concept, see e.g. [5] where interpolation between several asymptotically stabilizing feedback controllers is performed by minimizing an upper bound on the infinite horizon objective function. However, these results do not allow for priority among the interpolating control laws.

We provide, firstly, a necessary and sufficient condition for the positive invariance of an ellipsoid with respect to uncertain and/or time-varying systems with bounded additive disturbances. This invariance is an extension of a result in [6]. Secondly, a robust control method for constrained uncertain and/or time-varying systems subject to bounded disturbances is introduced, based on interpolation between r local unconstrained robust optimal controllers. It has three main features:

a) Recursive feasibility and input to state stability (ISS) are guaranteed for all feasible initial conditions. b) At each time instant, the solution of a quadratic programming (QP) problem of dimension $(r-1)(n+1)$ is required, where $n$ is the state dimension. c) With a block diagonal choice of the cost function matrix, the minimal robust positively invariant set for the performance controller is shown to be an attractor.

The paper is partially based on the conference contribution [7] where some further examples are found.

Notation: $I$ and $0$ denote the identity and zeros matrices, respectively, of appropriate dimensions. Whenever time is omitted, a variable $x$ stands for $x(k)$ for some $k \in \mathbb{N}$.

II. PROBLEM FORMULATION

Consider the following uncertain and/or time-varying linear discrete-time system,

$$x(k+1) = A(k)x(k) + B(k)u(k) + Ed(k)$$

(1)

where $x(k) \in \mathbb{R}^n$, $u(k) \in \mathbb{R}^m$ and $d(k) \in \mathbb{R}^d$ are, respectively, the measured state vector, the control input and the unknown additive disturbance. The matrices $A(k) \in \mathbb{R}^{n \times n}$, $B(k) \in \mathbb{R}^{n \times m}$ and $E \in \mathbb{R}^{n \times d}$. $A(k)$ and $B(k)$ satisfy

$$A(k) = \sum_{i=1}^{s} \alpha_i(k)A_i, \quad B(k) = \sum_{i=1}^{s} \alpha_i(k)B_i$$

(2)

where $\sum_{i=1}^{s} \alpha_i(k) = 1$, $\alpha_i(k) \geq 0$ and $A_i$, $B_i$ are given.

$x(k)$, $u(k)$ and $d(k)$ are subject to the following polytopic constraints

$$\left \{ \begin{array}{l} x(k) \in X, \quad X = \{ x \in \mathbb{R}^n : |F_{jx}x| \leq 1, \quad j = 1, \ldots, n_x \} \\ u(k) \in U, \quad U = \{ u \in \mathbb{R}^m : |u_j| \leq u_{j_{\text{max}}}, \quad j = 1, \ldots, m \} \\ d(k) \in D, \quad D = \{ d \in \mathbb{R}^d : |F_{jd}d| \leq 1, \quad j = 1, \ldots, n_d \} \end{array} \right.$$  

(3)

where $F_{jx}$ and $F_{jd}$ are respectively, the $j$-th row vector of the matrices $F_x \in \mathbb{R}^{n_x \times n}$ and $F_d \in \mathbb{R}^{n_d \times d}$, $u_{j_{\text{max}}}$ is the $j$-th component of the vector $u_{\text{max}}$. $F_{x}$ and $F_{d}$ and $u_{\text{max}}$ are assumed to be constant with $u_{\text{max}} > 0$ such that the origin is contained in the interior of $X$, $U$ and $D$.

A control law $u(k) = u(x(k))$ for (1) is to be designed such that the closed loop system is ISS w.r.t $d(k)$ with the constraints (3) satisfied.

III. PRELIMINARIES: ISS STABILITY AND SET INVARIANCE

Use will be made of $K$-functions, $K_{\infty}$-functions, KL-functions, ISS stability and ISS gain, and ISS Lyapunov functions as defined in [8].

Consider (1) with controller $u(k) = K x(k)$,

$$x(k+1) = A_e(k)x(k) + Ed(k)$$

(4)

where,

$$A_e(k) = A(k) + B(k)K = \sum_{i=1}^{s} \alpha_i(k)(A_i + B_iK).$$

(5)
Theorem 1 [8]: The system (4) is input-to-state stable if it admits an ISS-Lyapunov function.

**Definition 1:** (RPI) [1] A polyhedral set $\Omega \subseteq \mathbb{X}$ is a robustly constraint-admissible positively invariant (RPI) set w.r.t. (4), (3) iff, $\forall x(k) \in \Omega$ and $\forall d(k) \in D$, it holds that $A_c x(k) + E d(k) \in \Omega$ and $K x(k) \in U$.

$\Omega \subseteq \mathbb{X}$ is the maximal RPI (MRI) set for (4) and constraints (3) iff $\Omega$ is a RPI set and contains every MRI set. A non-empty MRI set is unique, see [1], where a constructive procedure is given to compute it in polyhedral form, $\Omega = \{x \in \mathbb{R}^n : F_0 x \leq g_0\}$.

**Definition 2:** (Invariant ellipsoid) An ellipsoid $E(P) = \{x \in \mathbb{R}^n : x^T P^{-1} x \leq 1\}$ is robustly positively invariant for (4) if $x(0) \in E(P)$ implies $x(k) \in E(P)$, $\forall k \geq 1$.

**IV. ROBUSTNESS ANALYSIS AND CONTROLLER DESIGN FOR INVARIANT ELLIPSOIDS**

**A. Robustness analysis**

Consider (1) with $u(k) = K x(k)$ yielding the closed loop (4). How to compute $K \in \mathbb{R}^{n \times n}$ will be shown below. Using the vertex representation of $D$, whereby $d(k) \in D$, one can find the smallest outer ellipsoid $E(P_d) = \{d \in \mathbb{R}^d : d^T P_d d \leq 1\}$, that contains $D$ [9]. Theorem 2 gives a necessary and sufficient condition for invariance of ellipsoids for system (4).

**Theorem 2:** $E(P)$ is invariant for (4) iff the $P \in \mathbb{R}^{n \times n}$ satisfies the following LMI condition, for some scalar $0 < \tau < 1$, $\forall i = 1, 2, \ldots, s$,

$$
\begin{bmatrix}
(1 - \tau) P & \tau P_d \\
\tau P_d & E^T P E
\end{bmatrix} \succeq 0,
$$

(6)

In order to prove the result we revisit the technique proposed in [6].

**Proof:** Denote $V(x) = x^T P^{-1} x$. For the invariance property of $E(P) = \{x(k) \in \mathbb{R}^n : V(x(k)) \leq 1\}$, it is required that $V(x(k + 1)) \leq V(x(k))$, and $\forall d(k) \in E(P_d)$, i.e. $(A_c x + E d)^T P^{-1} (A_c x + E d) \leq 1$, $\forall x, d$ such that $x^T P^{-1} x \leq 1$ and $d^T P d \leq 1$, or

$$
\begin{bmatrix}
x^T \\
d^T
\end{bmatrix}
\begin{bmatrix}
A_c^T P^{-1} A_c & A_c^T P^{-1} E \\
E^T P^{-1} A_c & E^T P^{-1} E
\end{bmatrix}
\begin{bmatrix}
x \\
d
\end{bmatrix} \leq 1
$$

(7)

such that

$$
\begin{bmatrix}
x^T \\
d^T
\end{bmatrix}
\begin{bmatrix}
0 & 0 \\
0 & P_d
\end{bmatrix}
\begin{bmatrix}
x \\
d
\end{bmatrix} \leq 1
$$

(8)

Using the $S$-procedure [10] with two quadratic constraints, (7), (8) is equivalent to,

$$
\begin{bmatrix}
A_c^T P^{-1} A_c & A_c^T P^{-1} E \\
E^T P^{-1} A_c & E^T P^{-1} E
\end{bmatrix} \succeq \begin{bmatrix}
\tau_1 P^{-1} & 0 \\
0 & \tau_2 P_d
\end{bmatrix}
$$

(9)

for some value of $\tau_1 > 0$, $\tau_2 > 0$, such that $\tau_1 + \tau_2 < 1$.

It holds that $A_c^T P^{-1} A_c > 0$ and $E^T P^{-1} E > 0$, since $P^{-1} > 0$. Clearly, the least restrictive right hand side of (9) is obtained by setting $\tau = \tau_2 = 1 - \tau_1$. Hence (9) is equivalent to the LMI

$$
\begin{bmatrix}
(1 - \tau) P & 0 \\
0 & \tau P_d
\end{bmatrix} - \begin{bmatrix}
A_c^T & E^T \\
A_c & E
\end{bmatrix} P^{-1} \begin{bmatrix}
A_c & E
\end{bmatrix} \succeq 0
$$

Using the Schur complement, one obtains

$$
\begin{bmatrix}
(1 - \tau) P & 0 \\
0 & \tau P_d
\end{bmatrix}
- \begin{bmatrix}
A_c^T & E^T \\
A_c & E
\end{bmatrix} P^{-1} \begin{bmatrix}
A_c^T \\
A_c
\end{bmatrix} \succeq 0
$$

or equivalently, for some scalar $0 < \tau < 1$,

$$
\begin{bmatrix}
(1 - \tau) P & 0 \\
0 & \tau P_d
\end{bmatrix}
- \begin{bmatrix}
A_c^T & E^T \\
A_c & E
\end{bmatrix} P^{-1} \begin{bmatrix}
A_c^T \\
A_c
\end{bmatrix} \succeq 0
$$

(10)

It follows from (5) that the left hand side of (10) is linear with respect to $\alpha_i(k)$. Hence one should verify (10) at the vertices of $\alpha_i(k)$, i.e. when $\alpha_i(k) = 0$ or $\alpha_i(k) = 1$. Therefore the LMI conditions to be satisfied are (6).

**Remark:** Theorem 2 extends the LMI condition in [6], where a similar condition was used to identify the minimal invariant ellipsoids for linear systems. The LMI (6) is a necessary and sufficient condition for ellipsoids to be invariant for uncertain and/or time-varying systems. In addition, (6) is applicable for generic ellipsoidal invariance, e.g. minimal, maximal, etc.

**B. Robust optimal design**

There are several conflicting objectives for designing a controller for system (1) with constraints (3). Usually, one would like to have an invariant ellipsoid with a large domain of attraction. It is well known [9] that by using the LMI technique, one can determine the largest invariant ellipsoid $E(P)$ with respect to the inclusion of some reference direction defined by $x_p$, meaning that the set $E(P)$ will include the point $\theta x_p$, where $\theta$ is a scaling factor. Indeed, $\theta x_p \in E(P)$ implies that $\theta^2 x_p^T P^{-1} x_p \leq 1$ or by using the Schur complement,

$$
\max_{P, \theta} \{\theta(\tau)\}
$$

(12)

subject to

- Invariance condition (6), which can be reformulated to be linear in $P$ and $Y$.
- Reference point inclusion (11).
- Constraint satisfaction [9].

On state:

$$
\begin{bmatrix}
P_j & 0 \\
0 & x_p^T P
\end{bmatrix} \succeq 0, \forall j = 1, 2, \ldots, n_x
$$

On input:

$$
\begin{bmatrix}
\theta^2 & 0 \\
0 & x_p^T P
\end{bmatrix} \succeq 0, \forall j = 1, 2, \ldots, m
$$
where \( Y = KP \in \mathbb{R}^{m \times n}, K_j \) is the \( j \)-th row of \( K \) and \( Y_j = K_jP \) is the \( j \)-th row of \( Y \).

Note that when \( \tau \) is fixed, the optimization problem (12) is an LMI problem, for which there nowadays exist several effective parsers and solvers, e.g., [11].

**Remark:** The reference points \( x_o \) can be chosen according to the available information on the initial conditions. For example, if some possible initial conditions are known, we can choose a set of reference points, that contains all these initial conditions.

V. INTERPOLATION BASED CONTROL

Using the results in the previous section, a set of robust asymptotically stabilizing controllers \( u = K_{t}x, \ t = 1, 2, \ldots, r \) is obtained such that \( A_{st}(k) = A(k)+B(k)K_{t} \) are robustly asymptotically stable and the corresponding MRPI sets \( \Omega_t \subset X \)

\[ \Omega_t = \{ x \in \mathbb{R}^n : F_{ot}x \leq g_{ot}, \ t = 1, 2, \ldots, r \} \]

are non-empty. Define \( \Omega \) as the convex hull of \( \Omega_t, \ t = 1, 2, \ldots, r \). It follows that \( \Omega \subset X \), since \( X \) is convex and \( \Omega_t \subset X, \ \forall t = 1, 2, \ldots, r \). The first controller in this enumeration will play the role of a performance controller, while the remaining controllers will be used for enlarging the domain of attraction.

A. Cost function determination

We use a similar decomposition of the state vector as the one in [12]. Any \( x(k) \in \Omega \) can be decomposed as,

\[ x(k) = \lambda_1(k)\hat{x}_1(k) + \sum_{t=2}^{r} \lambda_t(k)\hat{x}_t(k) \] \hspace{1cm} (13)

where \( \hat{x}_t(k) \in \Omega_t, \ \forall t = 1, 2, \ldots, r \) are decomposition variables and will be treated as decision variables, \( \lambda_t(k) \) are interpolating coefficients that satisfy \( \sum_{t=1}^{r} \lambda_t(k) = 1, \lambda_t(k) \geq 0, \ \forall t = 1, 2, \ldots, r \). Equation (13) can be rewritten as,

\[ x(k) = v_1(k) + \sum_{t=2}^{r} v_t(k) \] \hspace{1cm} (14)

with \( v_t(k) = \lambda_t(k)\hat{x}_t(k) \). Hence,

\[ v_1(k) = x(k) - \sum_{t=2}^{r} v_t(k) \] \hspace{1cm} (15)

Consider the following control law,

\[ u(k) = \lambda_1(k)K_1\hat{x}_1(k) + \sum_{t=2}^{r} \lambda_t(k)K_t\hat{x}_t(k) \]

\[ = K_1v_1(k) + \sum_{t=2}^{r} K_t v_t(k) \] \hspace{1cm} (17)

where \( K_t\hat{x}_t(k) \) is the control law in \( \Omega_t, \ \forall t = 1, 2, \ldots, r \).

Substituting (15) into (17), one gets

\[ u(k) = K_1 \left( x(k) - \sum_{t=2}^{r} v_t(k) \right) + \sum_{t=2}^{r} K_t v_t(k) \]

\[ = K_1 x(k) + \sum_{t=2}^{r} (K_t - K_1)v_t(k) \] \hspace{1cm} (18)

Using (18), one obtains,

\[ x(k+1) = A_{c1}(k)x(k) + B(k)\sum_{t=2}^{r} (K_t - K_1)v_t(k) + Ed(k) \] \hspace{1cm} (19)

where \( A_{c1}(k) = A(k) + B(k)K_1 \).

Define \( v_t(k+1), t = 2, 3, \ldots, r \) as

\[ v_t(k+1) = A_{ct}(k)v_t(k) + Ed_t(k) \] \hspace{1cm} (20)

with \( A_{ct}(k) = A(k) + B(k)K_t, \ d_t(k) = \lambda_t(k)d(k), \ \forall t = 2, 3, \ldots, r \).

Define also the vectors \( z \) and \( w \) as

\[ z = [ x^T \ v_2^T \ \ldots \ \ v_r^T ]^T, \ \ w = [ d_2^T \ d_3^T \ \ldots \ d_r^T ]^T \]

Writing (19), (20) in a compact matrix form, one obtains

\[ z(k+1) = \Phi(k)z(k) + \Gamma w(k) \] \hspace{1cm} (22)

where

\[ \Phi(k) = \begin{bmatrix} A_{c1}(k) & B(k)(K_2-K_1) & \ldots & B(k)(K_r-K_1) \\ 0 & A_{c2}(k) & \ldots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & A_{cr}(k) \end{bmatrix} \]

\[ \Gamma = \begin{bmatrix} E & 0 & \ldots & 0 \\ 0 & E & \ldots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & E \end{bmatrix} \]

From (2), it is clear that \( \Phi(k) \) can be expressed as a convex combination of \( \Phi_i \),

\[ \Phi(k) = \sum_{i=1}^{s} \alpha_i(k)\Phi_i \] \hspace{1cm} (23)

where \( \sum_{i=1}^{s} \alpha_i(k) = 1, \ \alpha_i(k) \geq 0 \) and \( \Phi_i \) is obtained from the vertices \( A_1, B_1 \).

Consider the following quadratic function,

\[ V(z) = z^T P z \] \hspace{1cm} (24)

where the matrix \( P \in \mathbb{R}^{r \times r}, \ P \succ 0 \) is chosen to satisfy

\[ V(z(k+1)) - V(z(k)) \leq -z(k)^T Q z(k) - u(k)^T Ru(k) + \sigma w(k)^T w(k) \]

with the weighting matrices \( Q \in \mathbb{R}^{r \times r}, \ R \in \mathbb{R}^{m \times m} \) and \( Q \succeq 0, \ R \succ 0, \ \sigma \geq 0 \).
Using (22), the left hand side of (25) can be written as,

\[ V(z(k+1)) - V(z(k)) = \]
\[ = (\Phi(k)z + \Gamma w)^T \mathcal{P} (\Phi(k)z + \Gamma w) - z^T \mathcal{P} z \]
\[ = [ z^T \ w^T ] \begin{bmatrix} \Phi^T(k) \\ \Gamma^T \end{bmatrix} \mathcal{P} \begin{bmatrix} \Phi(k) \\ \Gamma \end{bmatrix} \begin{bmatrix} z \\ w \end{bmatrix} - \]
\[ - [ z^T \ w^T ] \begin{bmatrix} \mathcal{P} & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} z \\ w \end{bmatrix} \]

and using (18), (21), the right hand side of (25) becomes,

\[ -x(k)^T Q x(k) - u(k)^T R u(k) + \sigma w(k)^T w(k) = \]
\[ = z(k)^T (-Q_1 - R_1) z(k) + \sigma w(k)^T w(k) \]
\[ = [ z^T \ w^T ] \begin{bmatrix} -Q_1 - R_1 & 0 \\ 0 & \sigma I \end{bmatrix} \begin{bmatrix} z \\ w \end{bmatrix} \]

where

\[ Q_1 = \begin{bmatrix} 1 & 0 \\ 0 & \Omega \end{bmatrix} \]
\[ R_1 = \begin{bmatrix} (K_2 - K_1)^T \\ \vdots \\ (K_r - K_1)^T \end{bmatrix} R \begin{bmatrix} K_1 & (K_2 - K_1) & \ldots & (K_r - K_1) \end{bmatrix} \]

One obtains, from (25), (26), (27),

\[ \Phi^T(k) \mathcal{P} \Phi(k) + \Gamma^T \mathcal{P} \Gamma \leq 0 \]

or equivalently

\[ \mathcal{P} - Q_1 - R_1 0 0 \]
\[ \begin{bmatrix} \Phi^T(k) & 0 \\ 0 & \sigma I \end{bmatrix} \mathcal{P} \begin{bmatrix} \Phi(k) \\ \Gamma \end{bmatrix} \begin{bmatrix} z \\ w \end{bmatrix} \geq 0 \]

(28)

Using the Schur complement, (28) can be brought to

\[ \begin{bmatrix} \mathcal{P} & Q_1 - R_1 0 \\ 0 & \sigma I \end{bmatrix} \begin{bmatrix} \Phi^T(k) & 0 \\ 0 & \sigma I \end{bmatrix} \mathcal{P} \geq 0 \]

(29)

Using (28), it is clear that (29) is feasible for \( \sigma \) sufficiently large if \( \Phi(k) \) is asymptotically stable.

The left hand side of (29) is linear with respect to \( \alpha_i(k) \) in (23). Hence one should verify (29) at the vertices of \( \alpha_i(k) \). Therefore the set of LMI conditions to be checked is as,

\[ \begin{bmatrix} \mathcal{P} & Q_1 - R_1 0 \\ 0 & \sigma I \end{bmatrix} \begin{bmatrix} \Phi^T(k) & 0 \\ 0 & \sigma I \end{bmatrix} \mathcal{P} \geq 0 \]

(30)

It is well known [8] that in the sense of the ISS gain having a smaller \( \sigma \) is a desirable property. The smallest value of \( \sigma \) can be found by solving the following LMI optimization problem,

\[ \min_{\mathcal{P}, \sigma} \{ \sigma \} \text{ subject to (30)} \]

(31)

B. Interpolation via quadratic programming

Once the matrix \( \mathcal{P} \) is computed as the solution of (31), it can be used in practice for real time control based on the resolution of a low complexity optimization problem. The resulting control law can be seen as a predictive control type of construction if the function (24) is interpreted as an upper bound for a receding horizon cost function.

At each time instant, for a given state \( x \), minimize on-line the quadratic cost function,

\[ V_1(z, \lambda_t) = \min_{z, \lambda_t} \{ z^T \mathcal{P} z + \sum_{t=2}^{r} \lambda_t^2 \} \]

subject to

\[ \begin{align*} \sum_{t=1}^{r} v_t & \leq \lambda_t g_{ot}, \quad \forall t = 1, 2, \ldots, r \\
\sum_{t=1}^{r} \lambda_t & = 1, \quad \lambda_t \geq 0 \end{align*} \]

and implement as input the control action (18).

Denote the optimal solution of the QP problem (32) as \( v_t^*(k) \) and \( \lambda_t^*(k) \) and define \( \tilde{x}_t^*(k) \) such that \( v_t^*(k) = \lambda_t^*(k) \tilde{x}_t^*(k) \), \( t = 1, 2, \ldots, r \). Then the following theorem holds.

**Theorem 3:** The control law (18), (32) guarantees recursive feasibility and the closed loop system is ISS for all initial states \( x(0) \in \Omega \).

**Recursive feasibility proof:** It has to be proved that \( u(k) \in U \) and \( x(k+1) \in \Omega, \forall x(k) \in \Omega \). Using (13), (17), (18) it follows that \( x(k) \) and \( u(k) \) can be expressed as,

\[ \begin{align*} x(k) & = \sum_{t=1}^{r} \lambda_t^*(k) \tilde{x}_t^*(k) \\
u(k) & = K_1 x(k) + \sum_{t=2}^{r} (K_t - K_1) v_t^*(k) = \sum_{t=1}^{r} \lambda_t^*(k) K_t \tilde{x}_t^*(k) \end{align*} \]

(33)

It thus holds that,

\[ u(k) = A x(k) + B u(k) + Ed(k) \]

\[ \leq \sum_{t=1}^{r} \lambda_t^*(k) u_{max} = u_{max} \in U \]

and,

\[ x(k+1) = A x(k) + B u(k) + Ed(k) \]

Since \( A x(k) + B u(k) + Ed(k) \in \Omega \), it follows that \( x(k+1) \in \Omega \).

**ISS stability proof:** From the feasibility proof, it is clear that if \( v_t^*(k) \) and \( \lambda_t^*(k) \) is the solution of (32) at time \( k \), then

\[ u_t(k+1) = A x_t(k) + B u_t(k) + Ed_t(k) \]

and \( \lambda_t(k+1) = \lambda_t^*(k) \) is a feasible solution of (32) at time \( k + 1 \). Solving (32) at time \( k + 1 \), one gets

\[ V_1(z(k+1), \lambda_t^*(k+1)) \leq V_1(z(k+1), \lambda_t(k)) \]
and by using inequality (25), it follows that
\[
V_1(z(k+1), \lambda_1^2(k+1)) - V_1(z(k), \lambda_1^2(k)) \leq -x(k)^T Q x(k) - u(k)^T R u(k) + \sigma u(k)^T w(k)
\]
Hence \( V_1(z, \lambda_1) \) is an ISS Lyapunov function of (22). It follows that the closed loop system with the control law (18), (32) is ISS.

Remark: Matrix \( P \) can be chosen as,
\[
P = \begin{bmatrix} S & 0 \\ 0 & S_r \end{bmatrix}
\] (34)
where \( S \in \mathbb{R}^{n \times n}, S_r \in \mathbb{R}^{(r-1)n \times (r-1)n} \). In this case, the cost function (32) can be written by
\[
V_1(z, \lambda_1) = x^T S x + s_r^T S_r s_r + \sum_{i=2}^r \lambda_i^2
\]
where \( s_r = [v_2^T \ v_3^T \ \ldots \ v_r^T]^T \). Hence, for any \( x(k) \in \Omega_1 \), the QP problem (32) has the trivial solution as \( v_i^T = 0 \) and \( \lambda_i^2 = 0, \forall t = 2, 3, \ldots, r \), and thus \( v_i^T = x \) and \( \lambda_i^2 = 1 \). This choice of \( P \) is advantageous if controller \( K_1 \) is designed for performance, while the other controllers are used to enlarge the domain of attraction.

\section{VI. EXAMPLE}
Consider the following uncertain linear discrete-time system,
\[
x(k+1) = A(k)x(k) + B(k)u(k) + d(k)
\] (35)
where
\[
A(k) = \alpha(k) A_1 + (1-\alpha(k)) A_2,
B(k) = \alpha(k) B_1 + (1-\alpha(k)) B_2
\]
\[
A_1 = \begin{bmatrix} 1 & 0.1 \\ 0 & 1 \end{bmatrix}, \quad B_1 = \begin{bmatrix} 1 \\ 0 \end{bmatrix},
A_2 = \begin{bmatrix} 1 & 0.2 \\ 0 & 1 \end{bmatrix}, \quad B_2 = \begin{bmatrix} 0 \\ 2 \end{bmatrix}
\]
\( \alpha(k) \in [0, 1] \) is an uncertain parameter. The constraints are:
\[
|z|_\infty \leq 10, \quad |u|_\infty \leq 1, \quad |d|_\infty \leq 0.1
\]
Three controllers are chosen as
\[
K_1 = [-1.8112 \ -0.8092], \quad K_2 = [-0.0878 \ -0.1176], \quad K_3 = [-0.0979 \ -0.0499]
\]
For \( Q = I \) and \( R = 1 \), by solving (31) with \( P \) in the form (34), one obtains \( \sigma = 41150 \) and
\[
S = \begin{bmatrix} 76.2384 & 11.4260 \\ 11.4260 & 3.6285 \end{bmatrix},
S_3 = \begin{bmatrix} 2468.4 & 1.6229 & -144.2 & 105.2 \\ 1622.9 & 1.6229 & -81.6 & -160.6 \\ -144.2 & -81.6 & 865.7 & 278.4 \\ 105.2 & -160.6 & 278.4 & 967.8 \end{bmatrix}
\]
Figure 1(a) shows the sets \( \Omega_1, \Omega_2 \) and \( \Omega_3 \) for the gains \( K_1, K_2 \) and \( K_3 \), respectively. Figure 1(b) presents state trajectories for different initial conditions and realizations of \( \alpha(k) \) and \( d(k) \). For the initial condition \( x_0 = [9.6145 \ 1.1772]^T \),

\section{VII. CONCLUSION}
The present paper proposes two contributions: first we provide an extension of the robust invariant condition for ellipsoids with respect to uncertain and/or time-varying systems with bounded additive disturbances. Thereafter a novel interpolation scheme is introduced. The interpolation is done between several unconstrained robust controllers. Among them, one controller is used for the performance, while the others are used for enlarging the domain of
attraction. The resulting control law guarantees recursive feasibility and ISS stability in the presence of constraints. A numerical example is presented to support the algorithms with illustrative simulations.
